**Molecular Weight Analysis of Polymers**

**Properties dependent on Molecular Weights and Molecular Weight Distributions (MWD)**

- Melt Viscosity
- Tensile Strength
- Toughness or Impact Strength
- Resistance to heat
- Corrosive Properties

---

**Average Molecular Weight ($\overline{M}$)**

\[
\overline{M} = \text{Average Number of Repeating Units } \overline{\bar{n}} \text{ or } \overline{\bar{d}_p}
\]
Examples:

1. Find $\bar{M}$ for

   \[
   \begin{array}{c}
   \text{Cl} \\
   \text{P} \\
   \text{N} \\
   \text{Cl}
   \end{array}
   \]

   if $n = 10,000$?

   \[
   \begin{align*}
   2 \times \text{Cl} &= 70.9 \\
   1 \times \text{P} &= 31.0 \\
   1 \times \text{N} &= 14.0
   \end{align*}
   \]

   Molecular Weight of repeating Unit = 115.9 \sim 116

   $\bar{M} = n \text{ or } dp \times \text{Mol. Weight of repeating units}$

   \[= 10,000 \times 116 = 11,600,00\]

2. Find $\bar{M}$ for

   \[
   \begin{array}{c}
   \text{F} \\
   \text{P} \\
   \text{N} \\
   \text{F}
   \end{array}
   \]

   if $n = 5,000$?

   Answer: 415,000
Representative Differential Weight Distribution Curve

- Relatively broad distribution
- Relatively narrow distribution
- Bimodal distribution curve

- Bimodal distribution is characteristic of polymerization occurring under two different pathways or environments.
**Number Average Molecular Weight**

Mathematically, in a mixture of polymer molecules with different molecular weights in which the number of molecules having a particular molecular weight, $M_i$, is given by $N_i$. The “number-average” probability ($P_i$) of a given mass being present is

$$P_i = \frac{N_i}{\sum_{j=0}^{\infty} N_j}$$

Indeed, the number-average molecular weight is given by the formula

$$\overline{M}_n = \sum_{i=0}^{\infty} \left( \frac{N_i}{\sum_{j=0}^{\infty} N_j} \right) M_i = \frac{\sum_{i=0}^{\infty} N_i M_i}{\sum_{j=0}^{\infty} N_j}$$

$\overline{M}_n$ is the arithmetic mean, representing the total weight of the molecules present divided by the total number of molecules. It is important to recognize that most thermodynamic measurements are based on the number of molecules present and hence depend on the number-average molecular weight: examples are the colligative properties, osmotic pressure and freezing point depression. End-group analysis is also used to calculate a value for $\overline{M}_n$.

**Example** : $\overline{M}_n$ for molecules having molecular weights of $1.00 \times 10^5$, $2.00 \times 10^5$, $3.00 \times 10^5$ would be, $6.00 \times 10^5 / 3 = 2.00 \times 10^5$
Colligative Properties

Dependent on the number of particles

Related to $\bar{M}_n$

$\bar{M}_n$ values are independent of molecular size
$M_n$ values are highly sensitive to small molecules present in the mixture.

$\bar{M}_n$ values are determined by Rault’s techniques that are dependent on “Colligative Properties”

(a) Ebulliometry (Boiling Point Elevation)
(b) Cryometry (Freezing point depression)
(c) Osmometry

Weight Average Molecular Weight

The probability factor in a weight-average considers the mass of the molecules so that the heavier molecules of the polymer segment are more important.

$$P_i = \frac{\sum_{j=0}^{\infty} N_j M_j}{\sum_{j=0}^{\infty} N_j M_j}$$

The weight average formula is derived as follows:
\[ M_w = \sum_{i=0}^{\infty} \left( \frac{N_i M_i}{\sum_{j=0}^{\infty} N_j M_j} \right) M_i = \frac{\sum_{i=0}^{\infty} N_i M_i^2}{\sum_{j=0}^{\infty} N_j M_j} \]

Molecular weight measurements take into consideration the contributions of molecules according to their sizes give weight-average molecular weights. Light scattering and ultracentrifuge methods are routinely used in the determination of \( \bar{M}_w \).

It is important to recognize that the weight-average molecular weight is larger than or equal to the number-average molecular weight. Indeed, the ratio of the weight-average and number-average molecular weights, \( \frac{M_w}{M_n} \), is a measure of the polydispersity of a polymer-mixture – this ratio is an index of how widely distributed the range of molecular weights are in the mixture.

**Average Molecular Weight (\( \bar{M}_z \))**

\[ \bar{M}_z = \frac{\sum_{i=1}^{N_i} M_i^3 N_i}{\sum_{i=1}^{N_i} M_i^2 N_i} \]
Example:

Size exclusion chromatographic data of a new polymer shows the following molecular weight distribution.

<table>
<thead>
<tr>
<th>Number of Molecules</th>
<th>Mass of each molecule</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>10,000</td>
</tr>
<tr>
<td>3</td>
<td>30,000</td>
</tr>
<tr>
<td>2</td>
<td>60,000</td>
</tr>
</tbody>
</table>

Calculate the number average ($\bar{M}_n$) and the weight average ($\bar{M}_w$) molecular weights of this polymer.

**Solution**: Number Average Molecular Weight:

Formula for the calculation of number average molecular weight:

$$M_n = \frac{\sum N_i M_i}{\sum N_i}$$

Remember the definition for the Number Average Molecular Weight: Number Average Molecular Weight is (The total weight of the sample)/(Number of molecules in the sample).

**Step 1**: You multiply the weight of the polymer molecule by the number of polymer molecules of that weight

$$\sum N_i M_i \text{ would be: } 5(1000) + 3(30,000) + 2(60,000) = 260,000$$

$$\sum N_i \text{ would be: } 5+3+2 = 10$$

Therefore, Number Average Molecular Weight $M_n = 260,000 / 10 = 26,000$

**Step 2**: Weight Average Molecular Weight ($M_w$)

Remember the formula for the calculation of weight average molecular weight $M_w$:

$$M_w = \frac{\sum N_i M_i^2}{\sum N_i M_i} = \frac{\sum W_i M_i}{\sum W_i}$$

The calculation of the weight average molecular weight requires that you know the weight fraction, $W_i$, of each type of polymer molecule. Weight fraction of individual polymer molecules is the mass of each polymer molecule ($N_i M_i$) divided by the total weight of the polymer ($\sum N_i M_i$).
Let us calculate $N_i M_i$, $\Sigma N_i M_i$ and the weight fraction ($W_i$) (that is $\frac{N_i M_i}{\Sigma N_i M_i}$) as follows:

<table>
<thead>
<tr>
<th>$N_i$</th>
<th>$M_i$</th>
<th>$N_i M_i$</th>
<th>$W_i = \frac{N_i M_i}{\Sigma N_i M_i}$</th>
<th>$M_i W_i$</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>10,000</td>
<td>50,000</td>
<td>0.192</td>
<td>1,920</td>
</tr>
<tr>
<td>3</td>
<td>30,000</td>
<td>90,000</td>
<td>0.346</td>
<td>10,380</td>
</tr>
<tr>
<td>2</td>
<td>60,000</td>
<td>120,000</td>
<td>0.461</td>
<td>27,660</td>
</tr>
</tbody>
</table>

$\Sigma N_i M_i = 260,000$

Weight Average Molecular Weight is $\Sigma W_i M_i = 39,960$

Note that $M_w > M_n$; and the ratio of $M_w/M_n$ is a measure of polydispersity.
Example:

For three molecules with molecular weights of $1.00 \times 10^5$, $2.00 \times 10^5$ and $3.00 \times 10^5$.

$\overline{M}_z$ would be $2.57 \times 10^5$

Melt elasticity of polymers is largely dependent on $\overline{M}_z$ values. In a polydisperse system $\overline{M}_w > \overline{M}_n$. $\overline{M}_w = M_n$ only in a monodisperse system.

**Polydispersity Ratio or Index:**

$\overline{M}_w / M_n$ is a measure of polydispersity; it is 2.0 for condensation polymers.
For a polymer mixture which is heterogeneous with respect to molecular weight distributions, $M_z > M_z > M_n$ with decrease in heterogeneity the various molecular weights will converge,

Finally, $M_z = M_z = M_n \rightarrow \text{Criterion for homogeneous polymer mixtures.}

**Molecular Weight Determination of Polymers**

1. Gel permeation Chromatography (GPC) Also called as Gel Filtration. This type of Liquid-Solid Elution Chromatography
   - Polymer fractions are separated on the basis of particle size
   - Smaller particles permeate the gel preferentially
   - The highest molecular weight fractions are eluted first
   - Polystyrene gel with pore sizes 1 to $10^6$ nm acts as a stationary phase.

The mixture of different sized polymer molecules is eluted in a solvent through a column of porous particles. The smaller molecules can enter the pores, whereas the larger molecules move out.
Gel Permeation Chromatography Apparatus

1. Injection Port
2. Column
3. Detector
4. Collector Flask
5. Chart Recorder
6. Solvent Reservoir
7. Pump with pressure gauge
Calibration Curve

The diagram shows a log-log plot with the following labels:
- X-axis: Elution Volume
- Y-axis: [\eta][M]

The graph includes points for:
- Polybutadiene
- Polystyrene
- Polyvinylchloride

The plot illustrates the relationship between elution volume and intrinsic viscosity times molecular weight.
Molecular Weight of Polystyrene standards in THF

Mathematically,

\[ \log[\eta]_X M_X = \log[\eta]_S M_S \] \hspace{1cm} (1)

Where,

\[ \eta = \text{intrinsic viscosity}, \ M = \text{Molecular Weight}, \ X = \text{Unknown polymer} \text{ and } S = \text{Standard Polymer} \]
Mark-Houwink Equation

K and a are constants,

Substituting (2) in (1) and solving the resulting expression for logM_X, (3) is obtained

\[ \log M_X = \frac{1}{(1+ax)} \log \left( \frac{K_S}{K_X} \right) + \frac{(1+a_S)/(1+a_X)}{\log M_S} \]  

Obtain the elution volume V_e for the unknown polymer from GPC and look for the corresponding logM_S value from the calibration curve. M_X is then determined from (3).
