Abstract  Public opinion regarding smoking and health has been of interest to polling companies since the 1940s. This article documents the rate of change in the public’s awareness and beliefs about smoking and health in North America (the United States and Canada). It reports on four broad categories of opinions: public awareness of reports that smoking has been linked to lung cancer; beliefs that smoking is harmful to health and a cause of lung cancer; beliefs that smoking is a cause of diseases other than lung cancer; and beliefs about the health hazards of secondhand smoke.

Public Concerns about Smoking and Health

This article documents the evolution of public attitudes and reported behavior related to smoking from 1950 to 2015—a period in which public health officials informed the public about the health risks associated with smoking. We draw upon a rich corpus of survey data on attitudes regarding smoking and health (Saad 1998; Pacheco 2011). This is a comprehensive overview of trends in public opinion concerning health and smoking that includes public opinion surveys from both Canada and the United States. A number of factors suggest that public opinion in the two countries trend in a similar fashion. These include strong similarities in media consumption (Grabb and Curtis 2010), and similar responses by policymakers to concerns regarding smoking and health. For example, the 1964 US Surgeon General’s report was closely followed in Canada by the Isabelle report that called for significant restrictions on the advertising and promotion of tobacco products (Isabelle 1969).
Awareness of Studies Linking Smoking and Lung Cancer

The 1950s saw increasing information that associated smoking with lung cancer, with scientific evidence appearing in leading academic journals (Doll and Hill 1950; Wynder and Graham 1950). The late 1950s marks the beginning of highly visible public pronouncements regarding the link between smoking and lung cancer. An example is the 1957 report on the health effects of smoking released by the American Cancer Society (Schmeck 1957).

Reports linking smoking and lung cancer attracted levels of public attention that are rarely recorded in public opinion data. For instance, 77 percent of the US population (and 82 percent of smokers) indicated that they had read or heard of the 1957 American Cancer Society report. As George Gallup pointed out at the time, this kind of attention to medical or scientific reporting is virtually unheard of—“a phenomenal figure in polling annals” (Gallup 1957).

Since the early 1950s, Gallup has asked the US and Canadian public whether they were aware of reports that smoking may be a cause of lung cancer. Table 1 indicates that awareness in the early 1950s was high: Gallup US asked the question twice in 1954. In one reading, 82 percent were aware of reports linking smoking to lung cancer, and in the second the result was 90 percent awareness. In 1954 Canadian awareness stood at 89 percent (Gallup Canada 1954). A 1964 survey conducted for the Canadian government found that 90 percent of Canadians were aware of reports that smoking is harmful (LaMarsh 1965). Awareness of studies reporting the link between smoking and lung cancer was high in the 1950s, and by the 1960s levels approached 90 percent in both countries.

Beliefs that Smoking Is Harmful to Health

Since the late 1940s, Gallup has asked whether cigarette smoking is harmful to health, with the item “Do you think cigarette smoking is or is not harmful?”

Table 1. Awareness That Smoking May Be a Cause of Lung Cancer.

Tables 2 and 3 present the results for the United States and Canada, respectively. In 1946, 42 percent of US smokers agreed with this statement, and in 1949, 60 percent of the US adult population thought that smoking is harmful. By 1977 this had risen to over 90 percent, reaching 95 percent in 1999. In Canada, beliefs about harmful effects and the hazards of smoking increased from 63 percent in 1961 to 97 percent in 1996.

Table 4 presents results for a similarly worded harm question that allowed for strength of agreement. In the early 1960s in the United States, 81 percent either strongly or mildly agreed that smoking is harmful to health. By 1975, this had risen to 90 percent (92 percent in Canada in 1996).

In 2002, US Gallup began asking adults about the extent to which smoking is harmful to one’s health. As table 5 indicates, from 2002 to 2015, roughly 80 percent consistently thought smoking is very harmful and 15 percent considered it somewhat harmful.

Between 1977 and 1987, US respondents were asked about the amount of smoking that would be harmful to health. As table 6 indicates, virtually no one thought smoking was not harmful; 59 percent answered that “any amount” is harmful in 1977, while 38 percent answered “only in excess.” These percentages shifted to 71 percent and 26 percent, respectively, in 1987.

The combined harm questions indicate how public acceptance that smoking is harmful for health has evolved over 70 years. In the United States, levels of agreement were about 42 percent in 1946. These levels rose to about two-thirds in the 1950s and early 1960s and reached over 85 percent from the mid-1960s onward. This trend is similar in Canada, although levels were slightly lower until the mid-1990s. In the early 1960s, about 60

percent of the population believed smoking is harmful to health, rising to over 75 percent in the late 1960s, and to over 85 percent by the late 1970s.

### Acceptance That Smoking Causes Lung Cancer

In the early 1950s, public health officials and the media became increasingly concerned and vocal about the link between smoking and lung cancer. Lung cancer represented one of the diseases that the average person most feared. In 1939, a US Gallup survey asked: “Which disease would you hate most to have?” From a list of four diseases, 76 percent of the respondents chose cancer, 13 percent tuberculosis, 9 percent heart trouble, and 2 percent pneumonia. In 1947, US Gallup asked an open-ended question: “What disease would you dread having most?” Fully 59 percent said cancer. No other disease was mentioned by more than 10 percent (Patterson 1987).

In 1954, Gallup began asking: “What is your own opinion—do you think cigarette smoking is one of the causes of lung cancer or not?” Table 7 presents US results for this variant of the lung cancer survey questions. The earliest available surveys (from 1954) showed that about 40 percent answered yes. From 1957 to 1960, about 50 percent of the US population indicated that they believed smoking is one of the causes of lung cancer. This had increased to 67 percent by the end of the decade. The trend continued upward, such that 81 percent agreed that smoking is one of the causes of lung cancer in 1977. After 1981, we identified 17 US surveys asking this question; with one exception (1998), 85 percent or more of the sample responded positively to this question.

*Less than .5%.
As table 8 indicates, responses to this lung cancer question were very similar in Canada. In 1954, 25 percent of Canadians surveyed answered “yes” to the question, and 16 percent provided a qualified answer. Incorporating information from the positive qualified responses results in an estimated 38 percent believing that smoking is one of the causes of lung cancer.\(^2\) In June 1963, 54 percent of Canadians surveyed said that smoking is “one of” the causes of getting lung cancer, and 22 percent said they did not know. In the late 1970s, almost 90 percent of Canadians agreed that smoking causes lung cancer. By the early 1980s, levels of agreement were over 90 percent, and this level persists through the 1990s, with only minor exceptions (1986 and 1988).

Respondents were asked about the likelihood that smoking causes lung cancer or the strength of its relationship to lung cancer. Table 9 indicates that about 65 percent of respondents to a 1966 US government survey definitely or probably considered smoking a major cause of lung cancer. In 1985, over 90 percent of US respondents thought smoking definitely or probably increased the chances of lung cancer. Canadian surveys during a similar time period echoed this trend.

Between 2000 and 2004, Environics asked Canadians how much they agreed with the statement that cigarette smoking may or may not cause lung cancer. Results in table 10 indicate that the “strongly agree” response always represents 87 percent or more of the sample.

In summary, approximately 40 percent of the North American population in the 1950s believed smoking is one of the causes of lung cancer. More than 50 percent of the public believed that smoking is one of the causes of lung cancer by the early 1960s, and this increased to 70 percent in the early 1970s. After 1981, most surveys indicated that over 90 percent of the North American population believed smoking is one of the causes of lung cancer.

\(^a\)Cigarette smoking is a major cause of lung cancer, a minor cause, or science hasn’t yet been able to tell what the relation is between cigarette smoking and lung cancer?

\(^b\)Tell me if you think cigarette smoking definitely increases, probably increases, probably does not, or definitely does not increase a person’s chance of getting lung cancer.

\(^c\)In your opinion, is smoking a major, medium, or minor factor in contributing to … [cancer of the lung]?
Beliefs about Smoking and Other Diseases

Public acceptance that smoking is one of the causes of lung cancer grew rapidly in the 1950s and 1960s. Public acceptance that smoking is one of the causes of other diseases was also high by the early 1960s, although not quite at the same levels as lung cancer. Public opinion organizations gauged the belief that smoking caused other diseases by asking them directly: “Do you agree that smoking has harmful effects on health (other than lung cancer)?” Table 11 indicates that three-quarters of a 1972 sample of young Canadians agreed that smoking has harmful effects on health (other than lung cancer).

<sup>a</sup>Smoking cigarettes can cause heart disease.

<sup>b</sup>Cigarette smokers are more likely to get heart disease than nonsmokers (definitely + probably).

<sup>c</sup>Smokers are more likely to get heart trouble.

<sup>d</sup>Smoking cigarettes causes heart disease.

<sup>e</sup>As far as you know, does smoking make coronary heart disease worse?

<sup>f</sup>Do you believe that smoking increases your risk of getting heart disease or not?

All samples are adults only except for <sup>e</sup> (smokers) and <sup>s</sup> (youths).

<sup>+</sup>less than .5%.
agreed with this statement; this had risen to 90 percent by 1981 (86 percent for a sample of parents).

In the 1950s, polling firms started asking about the link between smoking and other specific diseases. We focus on the most frequently asked heart disease question. Table 12 summarizes US responses to the question as to whether smoking is one of the causes of heart disease. In the period 1957 to 1959, levels of agreement were in the mid- to high-30 percent range. In 1964, the year the US Surgeon General’s report was released, agreement that smoking is one of the causes of heart disease reached 50 percent, another 28 percent responded “do not know,” and the remaining 22 percent did not agree. To compare, a US survey in the same year found that 62 percent of the population believed that smoking was probably linked to lung cancer—roughly a 10 percent spread.

In the early 1980s, over 70 percent of the population was aware that smoking is one of the causes of heart disease. Putting this in perspective, a 1981 US survey found that 83 percent believed that smoking is a cause of lung cancer. By the late 1980s, approximately 80 percent were aware of the link between smoking and heart disease. In the 1990s and 2000s, US survey results for this question ranged between 74 and 97 percent.

As table 13 indicates, in the 1980s an average of 77 percent of Canadian respondents agreed that smoking causes heart disease, which is similar to the United States. This increased to 94 percent of Canadians in 1996.

Heart disease questions asked between 1994 and 2004 in Canada adopted a strength of agreement format. Table 14 indicates that those agreeing strongly or somewhat made up over 80 percent of the sample in 1994 and over 90 percent in 2004. In the 1980s, Project Viking asked whether smoking is a major, medium, or minor factor in causing heart disease (see table 15); roughly 75 percent of respondents believed smoking was either a major or medium cause of heart disease. Overall, these surveys indicate that beliefs that smoking causes heart disease lagged about 10 percent behind those associating lung cancer with smoking. They rose from between 35 and 40 percent in the 1950s to over 60 percent in the 1970s and 80 percent in the 1980s.

\(^a\)Do you believe it is true that a smoker is twice as likely as a nonsmoker to die of heart disease?

\(^b\)Agree/disagree with risks of smoking including increased risk of heart disease?

\(^c\)What do you think are the health hazards related to firsthand smoking … [heart disease]?

\(^d\)What do you think are the health hazards related to firsthand smoking … [heart attacks]?

\(^e\)Smoking cigarettes can cause heart disease in a smoker.

All samples are adults only except for \(^p\) (parents), \(^y\) (youths), and \(^x\) (12–29-year-olds).
Beginning in 1974, Roper asked Americans: “Is smoking hazardous to non-smokers’ health?” As table 16 indicates, 46 percent agreed with this statement. In 1984, when it was last asked, 68 percent were in agreement. After that, US polling firms asked about the harmful health effects of secondhand smoke. In 1986, over 80 percent agreed that exposure of nonsmokers to smoke is harmful. This 80 percent agreement level remained relatively constant over the 1986-to-2000 period.

Table 16 reports results from the 1996 Canadian National Population Health Survey. Depending on the disease associated with secondhand smoke, agreement that it is a cause of the disease varies between 72 (heart disease) and 84 percent (asthma and breathing problems).

Table 17 reports results from survey questions that employed a strength of agreement response option. A 1992 US Harris study found that 65 percent of respondents “strongly” agreed that breathing someone else’s cigarette smoke

<sup>a</sup>How serious a health threat to you personally is the inhaling of secondhand smoke, often called passive smoking? Is it a very serious health threat, somewhat serious, not too serious, or not serious at all?

<sup>b</sup>How worried are you that your exposure to secondhand (cigarette) smoke might result in serious health problems for you someday?

<sup>c</sup>Secondhand smoke is very harmful to the health of others, somewhat harmful, a little harmful, not harmful at all, or no opinion?

All samples are adults only except for <sup>a</sup> (nonsmokers), <sup>p</sup> (parents), and <sup>y</sup> (youths).
is a real health hazard, and another 21 percent “somewhat” agreed. A 1979 Canadian Tobacco Manufacturing Council (CTMC) survey found that 40 percent of Canadians “strongly” agreed and 31 percent “somewhat” agreed that “Cigarette smoking is harmful to the health of non-smokers.” In 1994 this rose to 45 and 42 percent agreeing strongly and somewhat, respectively. Levels of agreement found in surveys conducted by Environics Canada in 2000 and 2001 ranged from 59 to 79 percent (heart disease) and 72 to 89 percent (lung cancer).

Table 18 presents results for secondhand smoke and health questions asked in a “severity of harm” format, with response options that include “very harmful,” “somewhat harmful,” “not too harmful,” and “not at all harmful.” Almost 70 percent of US respondents in the late 1980s indicated that the severity of harm from secondhand smoke was either very or somewhat harmful. By the late 1990s, about 85 percent responded either very or somewhat harmful. This 85 percent persisted throughout the period from 2001 to 2015. Health Canada surveys conducted in 1981 suggest that about 65 percent of parents and 75 percent of youths considered secondhand smoke either very or somewhat harmful to health.

Table 19 summarizes survey results about the seriousness of the health risks associated with secondhand smoke in Canada. In 2006, 77 percent indicated that nonsmoker exposure was a very serious harm, and 18 percent opted for somewhat serious harm. In 2004, a large majority indicated that exposure to secondhand smoke either definitely or probably contributed to lung cancer

*Please tell me whether you think secondhand smoke definitely, probably, probably not, or definitely not contributes to the following conditions [lung cancer].

*Please tell me whether you think secondhand smoke definitely, probably, probably not, or definitely not contributes to the following conditions [heart disease].

*Please tell me whether you think secondhand smoke definitely, probably, probably not, or definitely not contributes to the following conditions [asthma and breathing problem].

*The harm to the health of nonsmokers caused by breathing in secondhand smoke from cigarettes that other people are smoking is very serious, somewhat serious, not very serious, or not at all serious.
(92 percent), heart disease (86 percent), and asthma and breathing problems (89 percent). The US National Youth Tobacco Survey asked 9–21-year-olds to evaluate the likelihood of harm to themselves associated with secondhand smoke. Table 20 shows that for the period 1999 to 2011, roughly 70 percent answered “definitely yes” and another 20 percent responded “probably yes,” though these figures declined slightly in 2011.

In the 1970s, about half of the public believed that secondhand smoke is harmful to health. Public acceptance of the health hazards of secondhand smoke rose rapidly to 80 percent in the 1990s and 85 percent in the subsequent decade.

**Discussion**

US and Canadian attitudes toward smoking and health evolved similarly over this 70-year period. In the course of about 15 years—between 1954 and 1969—public belief that smoking is a cause of lung cancer rose from 40 to 70 percent. Attitudes regarding the link between smoking and other diseases responded with a slight lag. Nevertheless, in 1957 about 40 percent of the population believed smoking may cause heart disease, and by 1980 this had risen to 70 percent of the population. Public acceptance of the health hazards of secondhand smoke rose rapidly, from 50 percent in the 1970s to 80 percent in the 1990s.

**Appendix**

The surveys referenced below are all representative of the adult population of Canada or the United States, except in the case of youth (DNHW 1972; DNHW 1978; GOLDFARB 1981; GALLUP 1982; ENVIRONICS

3. The detailed citations appear in the online appendix.

Adults are defined as 18 years and over, except in the following samples: 15 years and over (DNHW 1964–65; EKOS 2004; EKOS 2006), 17 years and over (AUTS 1986; ROPERTI 1968–84), and 21 years and over (CCS 1961; CCS 1967; AUTS 1964; AUTS 1966; AUTS 1970; AUTS 1975).

**Interview Mode**

For face-to-face surveys, all households were determined by random walks within a designated area (e.g., GOLDFARB 1981). The non-telephone surveys conducted in AUTS 1975 were to allow greater representation of geographic areas with non-telephone households. All telephone surveys used random-digit dialing, unless otherwise noted. Interviews were conducted primarily in English but also in French for some Canadian provinces in the following surveys (DNHW 1972; STATCAN 1994; STATCAN 1996–97; GALLUP 1988; all ENVIRONICS; CTMC 1994).

**Response Rates**

Response rates were requested from all polling agencies; those surveys without response rates listed below are either unavailable or did not respond to the request. Polling agencies that reported a response rate, but not the methods used to calculate that rate, are designated “RR.” Respondents were randomly selected within households unless otherwise noted.
Poll Trends—Health and Smoking

AUTS 1964, 1966 (RR1: 82.0%), 1970, 1975, 1986 (RR1: 74.3%) (all random selection within household with smoker oversample)

CDC 2004 (RR: 82%), 2006 (RR: 80.2%), 2009 (RR: 84.8%), 2011 (RR: 73%)

CTMC 1994 (RR1: 26.4%)

DNHW 1978 (RR: 81.2%)

EKOS 2004 (RR1: 1.3%), 2006 (RR1: 9.7%)

ENVIRONICS 1999 (RR1: 19.8%), 2000 (RR1: 12.5%), March 2001 (RR1: 14.5%), April 2001 (RR1: 6.1%), 2003 (RR1: 7.0%), 2005 Adult (RR1: 11.4%), 2005 Youth (RR1: 3.9%)

GOLDFARB Pre-selection procedure determines respondent in household to be interviewed

IHIS > 90% of eligible households

NSF 1979–2000 (Cooperation rate: >70%), 2001 (Cooperation rate: 51%): most recent birthday selection method

STATCAN 1994–95 (RR1: 54.3%), 1996–97 (RR: 82.6%)
